

Safety of Spectacles for Children's Vision: A Cluster-Randomized Controlled Trial

XIAOCHEN MA, NATHAN CONGDON, HONGMEI YI, ZHONGQIANG ZHOU, XIAOPENG PANG, MIRJAM E. MELTZER, YAOJIANG SHI, MINGGUANG HE, YIZHI LIU, AND SCOTT ROZELLE

- **PURPOSE:** To study safety of children's glasses in rural China, where fear that glasses harm vision is an important barrier for families and policy makers.
- **DESIGN:** Exploratory analysis from a cluster-randomized, investigator-masked, controlled trial.
- **METHODS:** Among primary schools ($n = 252$) in western China, children were randomized by school to 1 of 3 interventions: free glasses provided in class, vouchers for free glasses at a local facility, or glasses prescriptions only (Control group). The main outcome of this analysis is uncorrected visual acuity after 8 months, adjusted for baseline acuity.
- **RESULTS:** Among 19 934 children randomly selected for screening, 5852 myopic (spherical equivalent refractive error ≤ -0.5 diopters) eyes of 3001 children (14.7%, mean age 10.5 years) had VA $\leq 6/12$ without glasses correctable to $> 6/12$ with glasses, and were eligible. Among these, 1903 (32.5%), 1798 (30.7%), and 2151 (36.8%) were randomized to Control, Voucher, and Free Glasses, respectively. Intention-to-treat analyses were performed on all 1831 (96.2%), 1699 (94.5%), and 2007 (93.3%) eyes of children with follow-up in Control, Voucher, and Free Glasses groups. Final visual acuity for eyes of children in the treatment groups (Free Glasses and Voucher) was significantly better than for Control children, adjusting only for baseline visual acuity (difference of 0.023 logMAR units [0.23 vision chart lines, 95% CI: 0.03, 0.43]) or for other baseline factors as well (0.025 logMAR units [0.25 lines, 95% CI 0.04, 0.45]).

- **CONCLUSION:** We found no evidence that spectacles promote decline in uncorrected vision with aging among children. (Am J Ophthalmol 2015;160(5):897–904. © 2015 by Elsevier Inc. All rights reserved.)

SOME HALF OF ALL DISABILITY AMONG CHILDREN IN the developing world is due to poor vision.¹ The leading and most readily treated cause of children's visual impairment (visual acuity [VA] $< 6/18$) is refractive error, affecting 12.8 million children aged 5–15 years worldwide, half of whom live in China.² Chinese children, for whom uncorrected refractive error accounts for 90% of visual impairment, have among the world's highest rates of myopia (near-sightedness).^{3,4} Uncorrected refractive error is associated with worse self-reported visual function among children,⁵ and provision of accurate spectacles improves children's functioning⁶ and educational outcomes.⁷ Spectacles provide an inexpensive and highly effective treatment for refractive error.

Despite the high prevalence and impact of children's refractive error in rural China, rates of spectacle ownership and wear remain as low as 15% among those needing them.⁷ Studies in China^{8,9} and elsewhere¹⁰ suggest that a major reason for this is the perception among children, parents, and teachers that glasses wear harms children's vision by worsening myopia. Concerns about the safety of glasses wear for children also influences policy makers. Government Health and Education Bureau websites in China may explicitly advise that children's glasses wear leads to vision problems,¹¹ or fail to recommend glasses as a treatment for myopia owing to safety concerns.¹²

It is known that accurately measured glasses improve the corrected VA, but the concern among many laypersons in China is that wearing glasses will eventually worsen a child's uncorrected VA, increasing dependence on their wear. It is this latter effect of glasses on the uncorrected vision that is not known. Previous small studies^{13–15} have been inconclusive on the effect of glasses wear on refractive power, and have not compared wear of glasses with nonwear, or directly reported effects on VA.

We carried out a large, cluster-randomized, population-based trial on the educational impact of providing spectacles to children with refractive error in rural China.⁷ We now report an exploratory, intention-to-treat analysis of the impact of assignment to receive access to free spectacles on uncorrected (without glasses) VA over the course of a school year, approximately 8 months.

Accepted for publication Aug 10, 2015.

METHODS

THE PROTOCOL FOR THIS STUDY WAS APPROVED IN FULL BY Institutional Review Boards at Stanford University (Palo Alto, California, USA) and the Zhongshan Ophthalmic Center of Sun Yat-Sen University (ZOC, Guangzhou, China). Permission was received from local Boards of Education in each region and from the principals of all schools. The principles of the Declaration of Helsinki were followed throughout. The original trial (Registration site: <http://isrctn.org>. Registration number: ISRCTN03252665) was designed to study the effect of providing free spectacles on children's educational performance, and found that scores on a study-specific mathematic test were statistically significantly higher in the group receiving free spectacles compared to controls.⁷

The hypothesis of the current exploratory analysis, based on our original trial data, is that provision of glasses would slow the decline in uncorrected VA expected to occur owing to increase in myopia (nearsightedness) commonly observed among children with aging.¹⁶ The primary outcome of the current analysis is uncorrected VA 8 months after provision of spectacles, adjusting for baseline VA. The choice of this outcome is based on the fact that uncorrected distance VA is expected to worsen with worsening myopia, and that vision itself, rather than refractive power, is the outcome of interest from the standpoint of disability and its alleviation. The methods of the original trial have been described previously⁷ and are provided here for reference.

• **SETTING, SAMPLING, AND ELIGIBILITY CRITERIA:** The study was carried out in 2 nearby areas of western China: Tianshui prefecture, a poor area in Gansu, one of China's poorest provinces,^{17,18} and Yulin prefecture, Shaanxi, a more affluent region in a middle-income province.^{17,19}

One school from each township in both prefectures was randomly selected from a list of all primary schools, and within each school, 1 class was randomly chosen in each of the fourth and fifth grades. For the original trial, all children at the 252 selected schools meeting the following criteria were eligible:

- Uncorrected (without glasses) VA $\leq 6/12$ in either eye
- Refractive error as follows:
 - myopia ≤ -0.75 diopters (D),
 - hyperopia $\geq +2.00$ D, or
 - astigmatism (nonspherical refractive error) ≥ 1.00 D
- VA could be improved to $>6/12$ in both eyes with glasses

In the current analysis, carried out by eye rather than child, all nonmyopic (refractive error > -0.5 D) eyes of eligible children were excluded (Figure 1).

• **QUESTIONNAIRES:** At baseline (September 2012: beginning of the school year), enumerators administered questionnaires to children concerning their age, sex, glasses wear, awareness of their refractive status,

boarding at school, and parental migration and education. A parental questionnaire asked about ownership of 13 selected items as an index of family wealth. Mathematics teachers were asked to state whether the blackboard was used for all teaching, most, about half, little, or none. At closeout (May–June 2013: end of the school year) children again filled out a questionnaire on glasses wear. Population density was calculated as the total population divided by total land area at the township level.

• **ASSESSMENT OF VISUAL ACUITY:** Children underwent baseline VA screening at school by a nurse and staff assistant, previously trained by optometrists from ZOC. VA was tested separately for each eye without refractive correction at 4 meters using Early Treatment Diabetic Retinopathy Study (ETDRS) charts²⁰ (Precision Vision, La Salle, Illinois, USA) in a well-lighted, indoor area. If the orientation of at least 4 of 5 optotypes on the 6/60 line was correctly identified, children were examined on the 6/30 line, on the 6/15 line, and then line by line to 6/3. If a line was failed, lines above were tested successively until the child identified 4 of 5 optotypes, with the VA for an eye defined as the lowest line read successfully. If the top line could not be read at 4 meters, the subject was tested as above at 1 meter, and the measured VA was divided by 4.

• **REFRACTION (MEASUREMENT OF GLASSES POWER):** Children with uncorrected VA $\leq 6/12$ in either eye underwent cycloplegia with up to 3 drops of cyclopentolate 1% and automated refraction (Topcon KR 8900; Tokyo, Japan) with subjective refinement by a refractionist, previously trained by experienced pediatric optometrists from ZOC.

• **RANDOMIZATION AND INTERVENTIONS:** This was a cluster-randomized, controlled trial, with schools as the clusters. In October 2012, after the baseline survey and vision screening but prior to refraction, eligible children were randomized by school to receive 1 of 3 interventions (Figure 1):

- Free spectacles based on the child's measured refractive power dispensed at school by the study optometrist (Free Glasses group, 84 schools);
- Vouchers bearing the child's name, school name, and glasses prescription, exchangeable for free glasses at the local county hospital (distance from children's township: range 1–105 km, median 30 km). Parents were responsible for paying transportation costs (Voucher group, 84 schools); or
- A glasses prescription and letter to the parents informing them of the refractive status of their child, with free glasses provided only at closeout, though this was not previously announced (Control group, 84 schools).

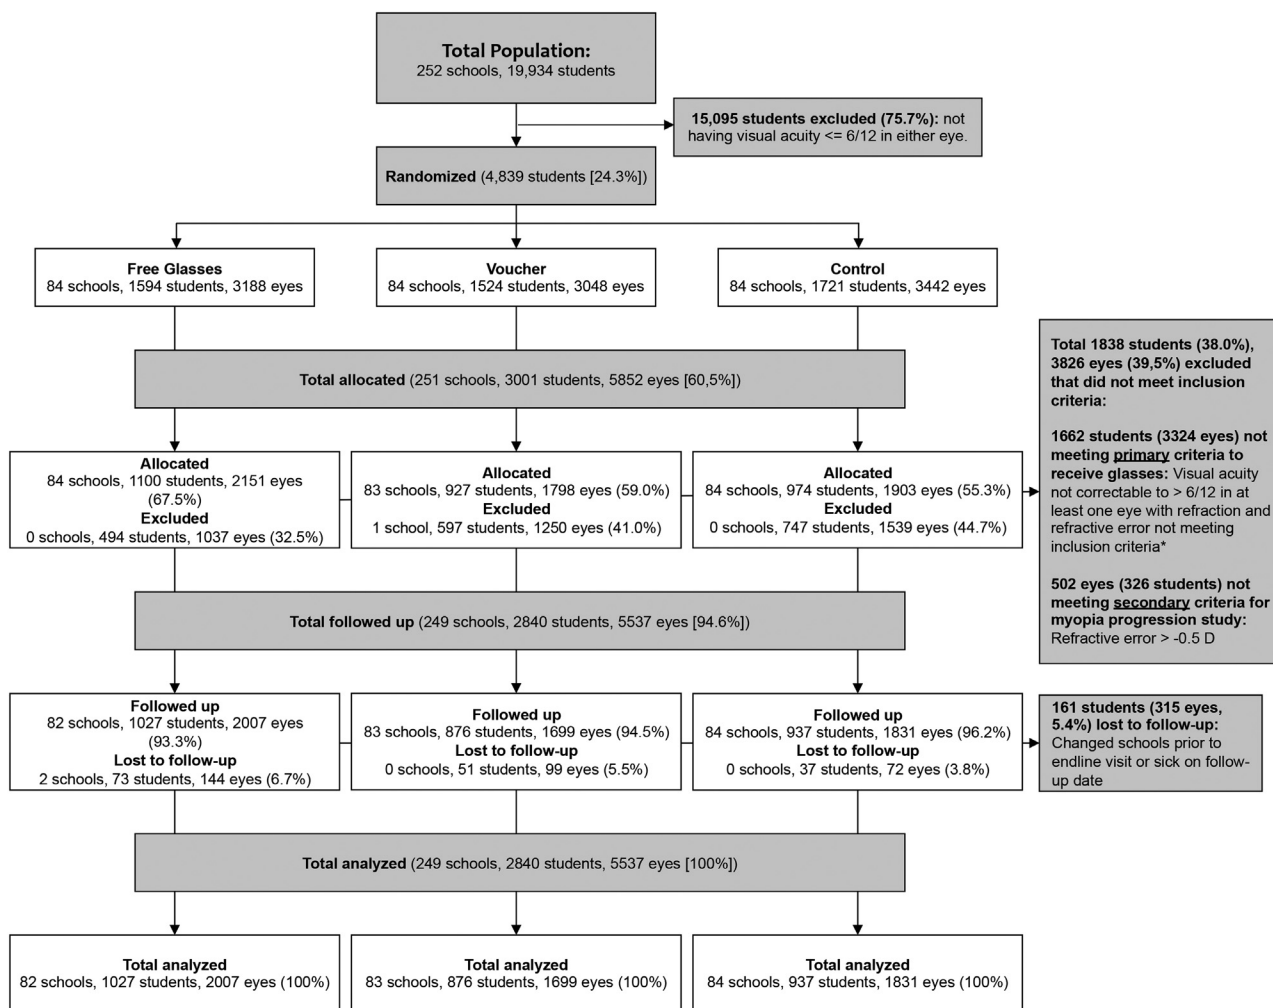

FIGURE 1. Enrollment and progress of children through a randomized trial on the effects of the provision of spectacles to Chinese school-age children.

Schools were stratified by size, county, and number of children failing VA screening. We used R software (R Foundation for Statistical Computing, Vienna, Austria) to generate blocks of and randomly allocate schools within each block to the treatment arms.

• **OUTCOME ASSESSMENT:** At closeout, VA was assessed using the protocol and vision chart described above. Spectacle wear was assessed through unannounced direct examinations on the same occasion. Children also described their own spectacle wear as “always,” “only for studying,” or “usually not worn.” Study personnel were masked to group assignment. Participants (students, parents, and teachers) and enumerators were not informed of either the overall design of the study or the explicit treatment arm assignment. During this visit, all children provided information on parental spectacle wear, and their own time spent out of doors and in near/middle distance work, important determinants of myopia progression.^{16,21,22}

• **STATISTICAL METHODS:** Family wealth was calculated by summing the value, as reported in the China Rural Household Survey Yearbook (Department of Rural Surveys, National Bureau of Statistics of China, 2013), of items on the list of 13 owned by the family. Refractive power was defined throughout as the spherical equivalent, the spherical power plus half the cylindrical power.

Randomization groups were compared by intention-to-treat (ITT) analysis using multiple linear regression, with end-line uncorrected VA (logarithm of the minimal angle of resolution [logMAR]) as main outcome and intervention arms and baseline uncorrected VA as covariates. Other baseline variables were also investigated as predictors for final VA, with the final model including intervention arms and variables associated with baseline VA at $P \leq .20$. Student and school were included in a random intercept model to adjust for the correlation between eyes of a student, between children in the same school, and between schools within

^b0.1 change in logMAR indicates 1 line change on the vision chart.

^cDefined as having glasses at school at baseline, having previously been told to bring them to school.

the same randomization block. All analyses were performed using Stata 12.0 (StataCorp, College Station, Texas, USA), and SAS 9.3 (SAS Institute, Cary, North Carolina, USA).

RESULTS

AMONG 19 934 CHILDREN SCREENED AT 252 SELECTED schools, 4839 (24.3%) failed VA screening and were randomized (Figure 1). Of these, a total of 3177 children

(65.7%) (6354 eyes) in 251 schools were eligible for allocation (VA improving with refraction). Among these, 5852 eyes (92.1%) of 3001 children (94.5%) were myopic; their baseline characteristics by treatment group are described in Table 1.

Intention-to-treat analyses were performed on all 1831 (96.2%), 1699 (94.5%), and 2007 (93.3%) eyes of children completing final VA assessment in the Control, Voucher, and Free Glasses groups (Figure 1). Those with follow-up did not differ in any baseline variables compared to those without (data not shown).

logMAR = logarithm of the minimal angle of resolution.

Though higher values on the logMAR scale indicate worse vision, we have followed the convention in this table that negative change indicates worsening and positive change indicates improvement.

^aExcept for the regression coefficient for baseline visual acuity (simple regression), coefficients for the different variables are for multiple models with end-line visual acuity as dependent variable, adjusted for baseline visual acuity.

^bIncluding variables associated with visual acuity $P \leq .20$ in the model only adjusted for baseline visual acuity.

^cA negative regression coefficient indicates an association with worse end-line visual acuity.

latter presumably indicating that children with better VA were less likely to wear glasses). Students in the 2 treatment groups combined had, on average, 0.025 logMAR units better final VA (0.25 lines, 95% CI 0.04, 0.45, $P = .02$) compared to children in the Control group. Time spent in near work and outdoor activity, boarding at school, glasses wear by parents, parental education and migration status, province of residence, family wealth, use of blackboard in classroom teaching, and population density of the township of residence were not significantly associated with end-line VA.

Only 15% (441/3001) of these children needing glasses were wearing them at baseline. End-line glasses wear was 42% (observed: 439/1053) to 69% (self-reported:

730/1053) in the Free Glasses group; 38% (observed: 334/887) to 65% (self-reported: 574/887) among the Voucher group; and 26% (observed: 241/944) to 38% (self-reported: 355/944) among Controls.

DISCUSSION

RESULTS FROM ITT ANALYSIS IN THIS RANDOMIZED TRIAL suggest that provision of spectacles does not promote the decline in uncorrected VA expected from increasing myopia with age¹⁶ among children. Concern over such

potential harm is widespread in China^{8–10} and has been identified as an important barrier to use of glasses by children needing them there^{8,9} and elsewhere.^{23,24}

This study provides the strongest evidence to date of the visual safety of spectacle wear for children. While the mean beneficial effect on VA of one-quarter line over a school year was modest, this effect size reflects all children randomized to receive treatment, whether glasses were used or not. Compliance rates in the treatment groups were 40%–70% and, conversely, a quarter to a third of children in the Control group had obtained glasses by the time of the final examination. Strategies to improve spectacle compliance could realize a greater impact on vision protection. We are currently testing teacher incentives as a means to improve children's classroom wear of glasses in a trial in Shanghai. The cumulative impact on vision protection over time may also be greater, though studies are needed to confirm this.

We searched the PubMed database in January 2014 for articles describing randomized trials in any language published since 1970, using the terms “correction,” “glasses,” and “spectacles” cross-indexed with “refractive error” and “myopia”; “change,” “decline,” “effect,” and “impact”; and “vision” and “visual acuity.” Two previous small (total of <200 children) trials^{14,15} compared the effect on change in refractive power over 18–24 months of full correction of refractive error with glasses to provision of glasses with power lower by 0.50–0.75 D than needed for optimal distance VA. The hypothesis of these studies was that lower-power glasses would be protective against the worsening of myopia with aging. The 2 studies actually found less progression of refractive error in the full-power group by 0.15 D,^{14,15} an effect that was significant when the results were pooled in a subsequent Cochrane review.¹³ These studies did not randomize children to go without glasses altogether, report on VA, or include many Chinese children (41 participants [44%] in Chung and associates¹⁵). Current sparse trial evidence is thus consistent in suggesting that correction of refractive error with glasses may be protective against, or is at least unlikely to worsen, declines in VA due to myopic progression with aging in children.

The factors underlying this tendency for myopia to worsen with age are not fully understood, but are thought to be controlled by dopaminergic pathways,²⁵ mediated by factors including time spent in near work and outdoors,^{16,21,22} and the stimulus of defocused light falling on the peripheral retina.²⁶ Wear of conventional spectacles does appear to contribute to this peripheral defocus,^{27,28} which provided

the impetus for the randomized trials of under-correction in preventing myopia progression as cited above.^{14,15} The mechanism whereby spectacle wear (compared to nonwear) appears in fact to retard worsening of vision associated with progression of myopia is not well understood.

Recent evidence suggests that optical correction designed specifically to prevent defocused light from falling on the peripheral retina may further retard age-related increase in myopic refractive error in children, when compared to conventional glasses and contact lenses.²⁹ These devices are still not widely available, and are quite expensive compared to conventional glasses. Though not at present appropriate for large-scale treatment programs, they may eventually offer an even greater vision protection benefit.

The strengths of the current study include its population-based sampling, randomized design, and high follow-up rates, all of which increase confidence in the results. Weaknesses must also be acknowledged: VA was not a prespecified outcome of trial, compliance with spectacle wear was less than perfect, and refractive power was not assessed at end line, precluding comparison of change in refractive power between groups over the study period. However, from the point of view of visual functioning and education, visual acuity rather than refractive error is the principal outcome of interest. All schools and children enrolled were drawn from 2 nearby prefectures in north-western China, so that application of these findings to other settings must be made with caution.

Uncorrected refractive error is the leading cause of visual impairment among children worldwide.² The results of this study provide strong evidence of the visual safety of medium-term spectacle wear for myopic children. Taken together with the main trial result demonstrating statistically significant improvements in educational outcomes with spectacle provision,⁷ the current result provides further impetus for programs to provide spectacles for children needing them, particularly in China where the myopia problem is greatest.

Previous randomized studies in China have shown that interventions aimed at explaining to children, their teachers, and their parents that glasses wear is beneficial and safe have had no³⁰ or very modest⁷ effects on uptake. A more immediate effect may be realized on policy makers concerned over spectacle safety:^{11,12} On the basis of our results to date,⁷ authorities in Shaanxi and Gansu Provinces, where the study was conducted, have already authorized county-wide models of free glasses distribution, with potential for expansion throughout both provinces.

FUNDING/SUPPORT: ONESIGHT (MASON, OHIO), LUXOTTICA-CHINA (SHANGHAI); ESSILOR-CHINA (SHANGHAI); CREDIT LYONNAIS Securities Asia (Asia Pacific Markets; Hong Kong); Charity Aid Foundation (Sydney); and an anonymous donor (Hong Kong). Dr Congdon is supported by a Thousand Man Plan grant from the Chinese government, and by the Ulverscroft Foundation. The free spectacles used in this study were supplied by OneSight, Luxottica-China, and Essilor-China, producers of frames and lenses in China, who also provided financial support for the study. Financial disclosures: The following authors have no financial disclosures: Xiaochen Ma, Nathan Congdon, Hongmei Yi, Zhongqiang Zhou, Xiaopeng Pang, Mirjam E. Meltzer, Yaojiang Shi, Mingguang He, Yizhi Liu, and Scott Rozelle. All authors attest that they meet the current ICMJE criteria for authorship.

The full dataset and statistical code are available at www.stanford.edu/REAP with open access. The presented data are anonymized and risk of identification is low.
